00T600" 66605950

In the conventional image processing system,
however, the total processing time (to be referred to
as a throughput hereinafter) required from the input of
an image to the end of printing mainly depends on the
5 data transfer time and the image processing time and
printing processing time in the image forming apparatus
side. Processing in the image input apparatus hardly
influences the total throughput.

This means that the operation of the image input
10 apparatus stops during the operation of the image
forming apparatus. The performance between the
apparatuses constituting the system is unbalanced.

SUMMARY OF THE INVENTION

15 The present invention has been proposed to solve
the conventional problems, and has as its object to
provide an image processing system which is constituted
by connecting an image input apparatus and image
forming apparatus to each other, and increases the
20 total throughput, a control method therefor, and an
image processing apparatus.

According to the present invention, the foregoing
object is attained by providing an image processing
system in which first and second image processing
25 apparatuses are connected via a serial bus, wherein the
first image processing apparatus comprises control

means for controlling distribution of image processing between the two apparatuses on the basis of performance of the first image processing apparatus and performance of the second image processing apparatus.

5 In accordance with the present invention as described above, the load of each apparatus can be distributed with good balance.

 According to the present invention, the foregoing object is attained by providing an image processing
10 system in which first and second image processing apparatuses are connected via a serial bus, wherein the first and second image processing apparatuses respectively comprise first and second control means for controlling distribution of image processing
15 between the two apparatuses, and determine which of the first and second control means acquires control.

 In accordance with the present invention as described above, which of the apparatuses acquires control of processing distribution can be appropriately
20 determined.

 According to the present invention, the foregoing object is attained by providing an image processing system in which first and second image processing apparatuses are connected via a serial bus, wherein
25 image data processed in the first image processing apparatus is stored in storage means under management

of the serial bus, and the second image processing apparatus selects either of the image data stored in the storage means and image data processed by the second image processing apparatus.

5 In accordance with the present invention as described above, either of image data processed by the respective apparatuses can be selected.

 According to the present invention, the foregoing object is attained by providing an image processing
10 system in which an image input apparatus and an image output apparatus are connected via a serial bus, wherein the image input apparatus comprises input means for inputting image data of a first format, determination means for determining whether to convert
15 the image data of the first format into a second format, first conversion means for converting the image data of the first format into the second format on the basis of a determination result, and first communication means for transmitting the image data of the first or second
20 format to the image output apparatus, and the image output apparatus comprises second communication means for receiving the image data transferred from the image input apparatus, holding means for temporarily holding the received image data in a buffer having a
25 predetermined capacity, second conversion means for, if the image data held in the buffer has the first format,

converting the image data into the second format; and
output means for sequentially outputting the image data
of the second format.

In accordance with the present invention as
5 described above, the format of transfer data between
the apparatuses can be properly changed.

The invention is particularly advantageous that
the total throughput increases in the image processing
system in which the image input apparatus and image
10 forming apparatus are directly connected.

Other features and advantages of the present
invention will be apparent from the following
description taken in conjunction with the accompanying
drawings, in which like reference characters designate
15 the same or similar parts throughout the figures
thereof.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated
20 in and constitute a part of the specification,
illustrate embodiments of the invention and, together
with the description, serve to explain the principles
of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Preferred embodiments of the present invention will now be described in detail in accordance with the accompanying drawings.

<First Embodiment>

Fig. 1 is a block diagram showing the arrangement of an image processing system to which the present invention is applied. Reference numeral 1 denotes a digital camera for inputting image data; and 2, a printer for printing out the image data input from the digital camera 1. The digital camera 1 and printer 2 are directly connected via a cable 16 by their interfaces (I/Fs) 3 and 4 defined by IEEE 1394.

The digital camera 1 is constituted by a CPU 5 for integrally controlling image input processing, a ROM 6 storing control programs executed by the CPU 5, a RAM 7 for temporarily storing data, an image input unit 8 for actually inputting image data, an image processing unit 9 for processing the input image data,

an interface (to be referred to as a "1394 serial bus") defined by the IEEE 1394-1995 standard (to be referred to as an "IEEE 1394"). The outline of the 1394 serial bus will be described below. Details of the IEEE 1394 standard are described in "IEEE Standard for a High Performance Serial Bus" published by IEEE (The Institute of Electrical and Electronics Engineers, Inc.), August 30, 1996.

10 [Outline of 1394 Serial Bus]

With the appearance of general digital video cam recorder (VCR) and digital video disk (DVD) player, there is a need for transferring realtime and large amount data such as video data and audio data (hereinafter referred to as "AV data"). To transfer AV data in realtime to a personal computer (PC) or other digital devices, an interface capable of high-speed data transfer is required. The 1394 serial bus has been developed from the above point.

20 Fig. 3 shows an example of a network system constructed with a 1394 serial bus. This system comprises devices A to H, and the devices A and B, the devices A and C, the devices B and D, the devices D and E, the devices C and F, the devices C and G, and the device C and H are respectively connected by a twisted pair cable for the 1394 serial bus. These devices A to

H may be computers such as a personal computer, or most computer-peripheral devices such as a digital VCR, a DVD player, a digital still camera, a storage device using a storage medium such as a hard disk or an optical disk, a monitor such as a CRT or an LDC, a tuner, an image scanner, a film scanner, a printer, a MODEM, and a terminal adapter (TA). Note that the printing method of the printer may be any method, e.g., a laser-beam printing, an electrophotographic method using an LED, an ink-jet method, a thermal-transfer method of ink melting or ink sublimation type and a thermo-sensitive printing method.

The connection between the devices may be made by mixedly using a daisy chain method and a node branching method, thus realizing high-freedom of connecting. The respective devices have an ID, and they construct a network by identifying each ID within a range connected by the 1394 serial bus. For example, the devices respectively take a relaying role only by daisy-chain connecting the devices with cables for the 1394 serial bus, thus constructing a network.

As the 1394 serial bus corresponds to Plug and Play function, it automatically recognizes a device connected to the cable, thus recognizes connection status. In the system as shown in Fig. 3, when a device is removed from the network, or a new device is

added to the network, the bus is automatically reset
(i.e., the current network constructing information is
reset), and a new network is constructed. This
function enables realtime setting and recognition of
5 network construction.

The 1394 serial bus has a data transfer speed
defined as 100/200/400 Mbps. A device having a high
transfer speed supports a lower transfer speed, thus
maintaining compatibility. As data transfer modes, an
10 asynchronous transfer mode (ATM) for transferring
asynchronous data such as a control signal, an
isochronous transfer mode for transferring isochronous
data such as realtime AV data are available. In data
transfer, within each cycle (generally 125 μ s/cycle), a
15 cycle start packet (CSP) indicating the start of cycle
is transferred, and then asynchronous and isochronous
data are mixedly transferred such that the isochronous
data transfer is transferred prior to the asynchronous
data.

20 Fig. 4 shows the construction of the 1394 serial
bus, as a layer structure. As shown in Fig. 4, a
connector port 810 is connected to a connector at the
end of a cable 813 for the 1394 serial bus. A physical
layer 811 and a link layer 812 in a hardware unit 800
25 are positioned as upper layers with respect to the
connector port 810. The hardware unit 800 comprises

interface chips. The physical layer 811 performs coding, connection-related control and the like, and the link layer 812, packet transfer, cycle-time control and the like.

5 In a firmware unit 801, a transaction layer 814
manages data to be transferred (transaction data), and
outputs commands Read, Write and Lock. A management
layer 815 in the firmware unit 801 manages connection
statuses and ID's of the respective devices connected
10 to the 1394 serial bus, thus manages the network
construction. The above hardware and firmware units
substantially constructs the 1394 serial bus.

In a software unit 802, an application layer 816 differs in software used by the system, and the data transfer protocol indicating how to transfer data on the interface is defined by a protocol such as a printer protocol or an AVC protocol.

Fig. 5 shows address space of the 1394 serial bus. All the devices (nodes) connected to the 1394 serial bus have a unique 64 bit address. The 64 bit address is stored in a memory of the devices. Data communication with a designated destination device can be performed by always recognizing the node addresses of the transmitting- and receiving-side nodes.

25 Addressing of the 1394 serial bus is made based
on the IEEE 1212 standards, such that first 10 bits are

described above. Next, the features of the 1394 serial bus will be described in more detail.

[Detail Description of 1394 Serial Bus]

5

[Electrical Specification of 1394 Serial Bus]

Fig. 6 shows a cross-section of the cable of the 1394 serial bus. The 1394 serial cable comprises two sets of twisted pair signal lines and two power-source lines. This construction enables power supply to a device which lacks a power source, or a device where a voltage is degraded due to a failure or the like. The direct-current voltage supplied by the power-source lines is 8 to 40V; the current is maximum 1.5 A. Note that in the standards for so-called DV cable, four lines except the power-source line construct the cable.

[DS-Link]

Fig. 7 is a timing chart explaining a DS-Link (Data/Strobe-Link) method as a data transfer method.

The DS-Link method, appropriate for high-speed serial data communication, requires two sets of two signal lines. That is, one of the two sets of twisted-pair signal lines is used for sending a data signal, and the other one set of twisted-pair signal lines is used for sending a strobe signal. On the

receiving side, an EXCLUSIVE-OR between the data signal and the strobe signal is obtained so as to generate a clock signal. In the DS-Link transfer, it is unnecessary to mix a clock signal into a data signal, therefore, transfer efficiency is higher than that in other serial-data transfer methods. Further, as a clock signal is generated from the data signal and the strobe signal, a phase locked loop (PLL) circuit can be omitted, which attains downsizing of the scale of a controller LSI. Further, in the DS-Link transfer, it is unnecessary to send information indicative of idle status when there is no data to be transferred, therefore, a transceiver of each device can be set in a sleep status, which reduces electric consumption.

15

[Bus-Reset Sequence]

The respective devices (nodes) connected to the 1394 serial bus are provided with a node ID, and are recognized as nodes constructing the network. For example, when increase/decrease of the number of nodes due to connection/disconnection or power ON/OFF status of network devices, i.e., network construction changes and it is necessary to recognize a new network construction, the respective nodes detect the change of network construction, send a bus-reset signal onto the bus, and enter a mode for recognizing the new network

25

construction. The detection of change of network construction is made by detecting change of bias voltage at the connector port 810.

When the bus-reset signal is sent from one node,
5 the physical layer 811 of the respective nodes receives the bus-reset signal, and at the same time, notifies the link layer 812 of the occurrence of bus reset, and forwards the bus-reset signal to the other nodes. When all the nodes have received the bus-reset signal, a
10 bus-reset sequence is started. Note that the bus-reset sequence is started when the cable is attached/detached, or the hardware unit 800 has detected network abnormality or the like. Further, the bus-reset sequence is also started by a direct instruction to the physical layer
15 811 such as host control by a protocol. As the bus-reset sequence is started, data transfer is suspended during the bus reset, and after the bus reset, the data transfer is restarted in the new network construction.

20

[Node-ID Determination Sequence]

After the bus reset, the respective nodes start to obtain a node ID so as to construct a new network construction. A general sequence from the bus reset to
25 node-ID determination will be described with reference to the flowcharts of Figs. 8 to 10. Fig. 8 is a

Fig. 9 is a flowchart showing the sequence from the monitoring of bus-reset signal (S101) to the root determination (S104) in detail. Fig. 10 is a flowchart showing the node-ID setting (S105 and S106) in detail.

5 In Fig. 9, at step S201, the occurrence of bus-reset signal is monitored, and as the bus-reset signal has occurred, the network construction is reset. Next, at step S202, as a first step for re-recognizing the reset network construction, the respective devices
10 reset its flag FL with data indicative of "leaf (node)". At step S203, the respective devices examine the number of ports, i.e., the number of other nodes connected to them. At step S204, based on the result of examination at step S203, the devices examine the number of
15 undefined (i.e., parent-child relation has not been determined) ports. The number of undefined ports is equal to that of the ports immediately after the bus reset, however, with the progress of determination of parent-child relation, the number of undefined ports
20 detected at step S204 decreases.

 Only actual leaf(ves) can declare parent-child relation immediately after the bus reset. Whether or not the node is a leaf is detected from the number of ports examined at step S203; i.e., if the number of
25 ports is "1", the node is a leaf. The leaf declares that "this node is a child, and the connected node is a

parent" at step S205, then terminates the operation.

On the other hand, a node that detected at step S203 that the number of ports is "two or more" is a "branch". Immediately after the bus reset, as

5 "undefined ports > 1" holds, the process proceeds to step S206, at which the flag FL is set with data indicative of "branch", then declaration of parent-child relation from another node is waited at step S207. When the parent-child relation is declared
10 from another node, the process returns to step S204 at which the branch examines the number of undefined ports. If the number of undefined ports is "1", the branch can declare at step S205 that "this node is a child, and the connected node is a parent" to the node connected
15 to the remaining port. If the number of undefined ports is still "two or more", the branch waits for declaration of parent-child relation from another node at step S207.

When any one of the branches (or exceptionally
20 leaf(ves) which delayed declaring a child) detects that the number of undefined ports is "0", the parent-child declaration of the overall network has been completed. The only one node that has "0" undefined port, i.e., the parent of all the nodes, sets the flag FL with data
25 indicative of a "root" at step S208. Then at step S209, the node is recognized as a root.

directly connected nodes. "parent" means a node at an upper level and "child" means a node at a lower level in the hierarchical structure. In Fig. 11, the node that first declared parent-child relation after the bus reset is the node A. As described above, nodes (leaves) where only one port is connected can start declaration of parent-child relation. That is, if the number of ports is "1", it is recognized that the node is the end of the network tree, i.e., a leaf. The declaration of parent-child relation is started from the leaf which has first taken action among these leaves. Thus, a port of the leave node is set as a "child", while the port of another node connected to the leave node is set as a "parent". In this manner, "child-parent" relation is sequentially set between the nodes A and B, between the nodes E and D, and between the nodes F and D.

Further, among upper nodes having a plurality of ports, i.e., branches, parent-child relation is sequentially declared with respect to upper node(s), from the node that first received declaration of parent-child relation from the leaf. In Fig. 11, first parent-child relation is determined between the nodes D and E and between the nodes D and F. Then the node D declares parent-child relation with respect to the node C, and as a result, a relation "child-parent" is set

between the nodes D and C. The node C, that has received the declaration of parent-child relation from the node D, declares parent-child relation with respect to the node B connected to the other port, thus

5 "child-parent" relation is set between the nodes C and B.

In this manner, the hierarchical structure as shown in Fig. 11 is constructed. The node B, that has finally become the parent at all the ports, is
10 determined as a root. Note that a network has only one root. In a case where the node B that has received declaration of parent-child relation from the node A immediately declares parent-child relation with respect to another node, the other node, e.g., the node C, may
15 be the root node. That is, any node may be a root depending upon timing of transmitting declaration of parent-child relation, and further, even in a network maintaining the same construction, a particular node is not always become a root.

20 As the root has been determined, the sequence of determining the respective node ID's is started. Each node has a broadcast function to notify its ID information to all the other nodes. ID information includes a node number, information on a connected
25 position, the number of ports, the number of ports connected to other nodes, information on parent-child

relation on the respective ports and the like.

As described above, the assignment of node numbers is started from the leaves. In numerical order, node number = 0, 1, 2,.... is assigned. Then, by the
5 broadcasting of ID information, it is recognized that the node number has been assigned.

As all the leaves have obtained a node number, node numbers are assigned to the branches. Similar to the assignment of node numbers to the leaves, ID
10 information is broadcasted from the branch that received a node number, and finally, the root broadcasts its ID information. Accordingly, the root always has the greatest node number.

Thus, as the ID setting of the overall
15 hierarchical structure has been completed and the network has been constructed, then the bus initialization is completed.

[Control Information for Node Management]

20 The CSR core as shown in Fig. 5 exists on the register as a basic function of the CSR architecture for node management. Fig. 12 shows the positions and functions of the registers. In Fig. 12, the offset is a relative position from "0xFFFFF0000000".

25 In the CSR architecture, the register for the serial bus is arranged from "0xFFFFF0000200". Fig. 13

shows the positions and functions of the registers.

Further, information on node resources of the serial bus is arranged from "0xFFFF0000800". Fig. 14 shows the positions and functions of the registers.

5 The CSR architecture has a configuration ROM for
representing functions of the respective nodes. The
configuration ROM has a minimum format and a general
format, arranged from "0xFFFFF0000400". As shown in
Fig. 15, the minimum format configuration ROM merely
10 shows a vendor ID which is a unique numerical value
represented by 24 bits.

As shown in Fig. 16, the general format configuration ROM has information on a node. In this case, the vendor ID in this format is included in a "root_directory". Further, "bus_info_block" and "root&unit_leaves" include unique device number including the vendor ID, represented by 64 bits. The device number is used after network reconstruction by bus reset operation, to continue recognition of the node.

[Serial Bus Management]

As shown in Fig. 4, the protocol of the 1394 serial bus comprises a physical layer 811, a link layer 812 and a transaction layer 814. This provides, as the serial bus management, a basic function for node

management and bus resource management, based on the CSR architecture.

Only one node which performs bus management (hereinafter referred to as "bus management node") exists on the same bus, and provides the other nodes on the serial bus with management function which includes cycle master control, performance optimization, power source management, transmission speed management, construction management and the like.

The bus management function briefly divides into a bus manager, an isochronous resource manager and a node control function. The node control is a management function which enables communication among the nodes in the physical layer 811, the link layer 812, the link layer 812, the transaction layer 814 and an application program by the CSR. The isochronous resource manager, which is a management function necessary for isochronous-type data transfer on the serial bus, manages assignment of transfer bandwidth and channel number to isochronous data. For this management, after bus initialization, the bus management node is dynamically selected from nodes having the isochronous resource manager function.

Further, in a construction without a bus management node on the bus, a node having the isochronous resource manager function performs a part

of the bus management such as the power source management and cycle master control. Further, the bus management is a management function as service to provide a bus control interface to an application program. The control interface uses a serial-bus control request (SB_CONTROL.request), a serial-bus event control confirmation (SB_CONTROL.confirmation) and a serial-bus event indication (SB_EVENT.indication).

The serial-bus control request is used when an application program requires the bus management node to perform bus reset, bus initialization, representation of bus-status information, and the like. The serial-bus event control confirmation is the result of the serial-bus control request, and is notified from the bus management node to the application for confirmation. The serial-bus event control confirmation is made as notification of an synchronously-caused event from the bus management node to the application.

20

[Data Transfer Protocol]

The data transfer by using the 1394 serial bus simultaneously sends isochronous data (isochronous packet) which must be periodically transmitted, and asynchronous data (asynchronous packet) which can be transmitted/received at arbitrary timing, further,

ensures real-time transmission of isochronous data. In the data transfer, a bus use right is requested prior to transfer, and bus arbitration is performed to obtain bus use permission.

5 In the asynchronous transfer, a transmitting node ID and a receiving node ID are sent with transfer data as packet data. The receiving node confirms the receiving node ID, i.e., its node ID, receives the packet, and returns an acknowledge signal to the
10 transmitting node. Thus, one transaction is completed.

 In the isochronous transfer, a transmitting node requires an isochronous channel with a transmission speed, and a channel ID is sent with transfer data as packet data. A receiving node confirms a desired
15 channel ID and receives the data packet. The necessary channel number and transmission speed are determined by the application layer 816.

 These transfer protocols are defined by the physical layer 811, the link layer 812 and the
20 transaction layer 813. The physical layer 811 performs physical and electrical interface with the bus, automatic recognition of node connection, bus arbitration for a bus use right among nodes, and the like. The link layer 812 performs addressing, data
25 checking, packet transmission/reception and cycle control for isochronous transfer. The transaction

asynchronous data or isochronous data to be transferred has been detected. So far as the node has not detected the predetermined gap length, it cannot request a bus use right to start data transfer, accordingly, the node
5 waits until the predetermined gap length has been detected.

When the predetermined gap length has been detected at step S401, the node determines whether or not there is data to be transferred at step S402. If
10 YES, it issues a signal requesting a bus use right to the root at step S403. As shown in Fig. 17, this signal requesting the bus use right is relayed by the respective devices in the network, and forwarded to the root. If it is determined at step S402 that there is
15 no data to be transferred, the process returns to step S401.

At step S404, if the root has received a single or plurality of request signals for the bus use right, it examines the number of nodes requesting the bus use
20 right at step S405. From the determination at step S405, if the number of the nodes requested the bus use right is one, that node is provided with bus use permission immediately after the requirement. On the other hand, if the number of the nodes is more than one,
25 arbitration is performed to determine one node to be provided with the bus use right immediately after the

requirement. The arbitration does not always provide a bus use right to the same node, but equally provides a bus use right to the respective nodes (fair arbitration).

5 The processing at the root branches at step S407
into processing for the node dominated in the
arbitration at step S406, and processing for the other
nodes lost in the arbitration. In a case where there
is one node that requested the bus use right, or one
10 node has dominated in the arbitration, the node is
provided with an permission signal indicative of bus
use permission at step S408. The node starts data
(packet) transfer immediately after it receives the
permission signal (step S410). On the other hand, the
15 nodes lost in the arbitration receive a DP (data
prefix) packet indicative of rejection of the bus use
request at step S409. The processing for the node that
received the DP packet returns to step S401 to request
a bus use right again. Also, the processing for the
20 node that completed data transfer at step S410 returns
to step S401.

[Transaction Layer]

The transaction layer includes a read transaction,
25 a write transaction and a lock transaction.

In a read transaction, an initiator (requiring

(LK_DATA.request) to require packet transfer from the response node, a link indication (LK_DATA.indication) indicating packet reception to the response node, a link response (LK_DATA.response) as acknowledgment transmitted from the response node, a link confirmation (LK_DATA.confirmation) as confirmation of the acknowledgment transmitted from the response node.

One packet transfer process is called a sub-action including an asynchronous sub-action and an isochronous sub-action. Hereinbelow, the respective operations of the sub-actions will be described.

[Asynchronous Sub-action]

The asynchronous sub-action is asynchronous data transfer. Fig. 22 shows transition in the asynchronous transfer. In Fig. 22, the first sub-action gap represents the idle status of the bus. At a point where the idle time has become a predetermined value, a node which is to perform data transfer requests a bus use right, then bus arbitration is executed.

When the use of bus has been allowed by the arbitration, data in the form of packet is transferred, and a node which receives the data sends a reception acknowledgment code ACK as a response, or sends a response packet after a short gap called ACK gap, thus the data transfer is completed. The code ACK comprises

4-bit information and a 4-bit checksum. The code ACK, including information indicative of success, busy or pending status, is immediately sent to the data-sender node.

5 Fig. 23 shows a packet format for asynchronous transfer. The packet has a data area, a data CRC area for error correction, and a header area in which a destination node ID, a source node ID, a transfer data length and various codes are written.

10 The asynchronous transfer is one-to-one communication from a sender node to a receiver node. A packet sent from the sender node is relayed by the respective nodes in the network, however, as these nodes are not designated as the receiver of the packet,
15 they ignore the packet, then only the receiver node designated by the sender node receives the packet.

[Isochronous Sub-action]

 Isochronous transfer, which can be regarded as
20 the greatest feature of the 1394 serial bus is appropriate to multimedia data transfer which requires realtime transfer of, especially, AV data. Further, the asynchronous transfer is one-to-one transfer, whereas the isochronous transfer is broadcasting
25 transfer from one sender node to all the other nodes.

 Fig. 24 shows transition in the isochronous

transfer. The isochronous transfer is executed on the bus in a predetermined cycle, called "isochronous cycle". The period of the isochronous cycle is 125 μ s. A cycle start packet (CSP) 2000 indicates the start of the isochronous cycle for asynchronizing the operations of the respective nodes. When data transfer in a cycle has been completed and a predetermined idle period (sub-action gap 2001) has elapsed, a node which is called "cycle master" sends the CSP 2000 indicative of the start of the next cycle. That is, this interval between the issuance of CSP's is 125 μ s.

As channel A, channel B and channel C in Fig. 24, the respective packets are provided with a channel ID, so that plural types of packets can be independently transferred within one isochronous cycle. This enables substantially-realtime transfer among the plural nodes. The receiver node can receive only data with a predetermined channel ID. The channel ID does not indicate an address of the receiving node, but merely indicates a logical number with respect to the data. Accordingly, one packet sent from a sender node is transferred to all the other nodes, i.e., broadcasted.

Similar to the asynchronous transfer, bus arbitration is performed prior to the packet broadcasting in isochronous transfer. However, as the isochronous transfer is not one-to-one communication

like the asynchronous transfer, the reception acknowledgment code ACK used as a response in the asynchronous transfer is not used in the isochronous transfer.

5 Further, an isochronous gap (iso gap) in Fig. 24 represents an idle period necessary for confirming prior to isochronous transfer that the bus is in idle status. If the predetermined idle period has elapsed, bus arbitration is performed with respect to node(s)
10 desiring isochronous transfer.

Fig. 25 shows a packet format for isochronous transfer. Various packets divided into channels respectively have a data field, a data CRC field for error correction and a header field containing
15 information such as a transfer-data length, a channel No., various codes and error-correction header CRC as shown in Fig. 26.

[Bus Cycle]

20 In practice, both isochronous transfer and asynchronous transfer can be mixedly performed on the 1394 serial bus. Fig. 27 shows transition in the isochronous transfer and asynchronous transfer mixedly performed on the 1394 serial bus.

25 The isochronous transfer is performed prior to the asynchronous transfer because after the CSP, the

isochronous transfer can be started with a gap
(isochronous gap) shorter than the idle period
necessary for starting the asynchronous transfer.
Accordingly, the isochronous transfer has priority over
5 the asynchronous transfer.

In the typical bus cycle as shown in Fig. 27,
upon starting the cycle #m, a CSP is transferred from
the cycle master to the respective nodes. The
operations of the respective nodes are asynchronized by
10 this CSP, and node(s) that waits for a predetermined
idle period (isochronous gap) to perform isochronous
transfer participates in bus arbitration, then starts
packet transfer. In Fig. 27, a channel e, a channel s
and a channel k are transferred by the isochronous
15 transfer.

The operation from the bus arbitration to the
packet transfer is repeated for the given channels, and
when the isochronous transfer in the cycle #m has been
completed, the asynchronous transfer can be performed.
20 That is, when the idle period has reached the
sub-action gap for the asynchronous transfer, node(s)
that is to perform the asynchronous transfer
participates in bus arbitration. Note that only if the
sub-action gap for starting the asynchronous transfer
25 is detected, after the completion of isochronous
transfer and before the next timing to transfer the CSP

(cycle synch), the asynchronous transfer can be performed.

In the cycle #m in Fig. 27, the isochronous transfer for three channels is performed, and then two
5 packets (packet 1 and packet 2) including ACK are transferred by the asynchronous transfer. When the asynchronous packet 2 has been transferred, as the next cycle synch point to start the subsequent cycle m+1 comes, the transfer in the cycle #m ends. Note that
10 during the asynchronous or isochronous transfer, if the next cycle synch point to transfer the next CSP has come, the transfer is not forcibly stopped but continued. After the transfer has been completed, a CSP for the next cycle is transferred after a
15 predetermined idle period. That is, when one isochronous cycle is continued for more than 125 μ s, the next isochronous cycle is shorter than the reference period 125 μ s. In this manner, the isochronous cycle can be lengthened or shortened based
20 on the reference period 125 μ s.

However, it may be arranged such that the isochronous transfer is performed in every cycle, while the asynchronous transfer is sometimes postponed until the next cycle or the cycle further subsequent to the
25 next cycle, so as to maintain realtime transfer. The cycle master also manages information on such delay.

The IEEE 1394 serial bus used in this embodiment has been described. Characteristic control in the first embodiment will be explained.

5 [Arbitration Method/ Distribution Control of Image Processing]

The system arrangement shown in Fig. 1 can realize higher-speed data communication by connecting the digital camera 1 and printer 2 in one-to-one
10 correspondence using a 1394 serial bus having the above-described arrangement and functions. In the first embodiment, data is asynchronously transferred between the digital camera 1 and the printer 2. In this system, the digital camera 1 has higher
15 performance than the printer 2, so that the first embodiment can distribute image processing which should be generally performed by the printer 2 to the digital camera 1.

In the system of the first embodiment, the
20 digital camera 1 and printer 2 can equally execute distribution control of image processing using the peer-to-peer feature of the 1394 serial bus, and either apparatus can take the initiative of this control.

In the first embodiment, an apparatus having the
25 node ID = 0 can take the initiative based on the node ID of each apparatus set by bus reset in connection.

sequence of printing processing in the first embodiment. The left side of Fig. 28 shows processing in the digital camera 1, and the right side shows processing in the printer 2. The first embodiment can execute five roots A to E (to be described later) as processing sequences.

The digital camera 1 performs image generation processing at step S3101 in order to input a sensed image, compresses the generated image data at step

10 S3102, and then stores it in a memory such as the RAM 7.

● Process of Root A

The process of root A as the most general root will be explained. In executing the process of root A, the process branches at step S3103 to the root A side to read out image data from the memory at step S3104 and transfer the image data to the printer 2.

At step S3105, the printer 2 decompresses the image data transferred via root A. In general, image data generated by a digital camera or the like is processed as a compressed file which is advantageous in the memory use capacity and transfer time. Hence, the compressed file must be decompressed by the printer 2 at step S3105. When uncompressed image data is received, the data need not be decompressed.

The image data undergoes at step S3106 image data

5

15

20

25

25

printing operation at step S312 on the basis of the transferred image data.

Roots B to E shown in Fig. 28 execute transfer processing (S3111, S3114, S3117, and S3119) after
5 decompression processing at step S3109, so that the data amount to be transferred increases in comparison with transfer processing (S3104) of root A. The transfer time is, therefore, the shortest in root A.

As shown in the flowchart of Fig. 28, image
10 processing in the first embodiment selectively executes any one of roots A to E. A root selection method in the first embodiment will be described in detail.

● Process of Root Selection

15 Fig. 29 is a flowchart showing root selection processing in the first embodiment. This selection processing is executed under the control of the CPU 5 in the digital camera 1 which has taken the initiative by the above arbitration.

20 After printing processing starts, the digital camera 1 reads the configuration ROM of the printer 2 at step S3201, and specifies the model of printer based on the contents. Note that the configuration ROM has already been read in connecting the apparatus, and if
25 its contents are stored in a memory or the like, the stored contents are read out.

At step S3202, whether the digital camera 1 holds information about the model of printer specified at step S3201 is checked. If YES at step S3202, the process branches to S3203; and if NO, to step S3204.

5 If NO at step S3202, the digital camera 1 issues
a processing time calculation request to the printer 2
at step S3204. This request is asynchronously
transferred on the 1394 serial bus. After the digital
camera 1 requests the response of the results and
10 receives the calculation results, the digital camera 1
calculates the processing time of each processing.
Then, the process proceeds to step S3205. The printer
2 which has received the processing time calculation
request calculates the processing time of each
15 processing in the printer 2 described with reference to
Fig. 28 in accordance with an image to be printed.
Upon the completion of calculation, the printer 2
returns each processing time to the digital camera 1.

If YES at step S3202, the digital camera 1
calculates at step S3203 the processing time of each
processing in the digital camera 1 described with
reference to Fig. 28 in accordance with an image to be
printed. Then, the process proceeds to step S3205.

At step S3205, the digital camera 1 calculates
25 the total processing time of each of roots A to E shown
in Fig. 28. The digital camera 1 selects a root

exhibiting the shortest total processing time at step S3206, and notifies the printer 2 of the selection result at step S3207 to cause the printer 2 to prepare for printing.

Image processing and transfer processing shown in Fig. 28 start by the selected root exhibiting the shortest total processing time.

Calculation of the total processing time of each root at step S3205 is done as follows. When each
10 processing shown in Fig. 28 is to be performed in units of blocks of image data, given processing ends for all the data in one block, and then the block is subjected to the next processing. Based on this assumption, the total processing time can be calculated by simple
15 addition. Root selection in this case greatly depends on the performance of a CPU or the like and the transfer processing speed in each apparatus.

In practice, however, each processing is often executed in units of small blocks prepared by dividing one block of image data. When given processing is executed for one block of image data, the processing results are sequentially transmitted to the next processing in units of small blocks having undergone the processing. This realizes immediate processing in units of small blocks depending on the contents of the next processing, and two processes are

parallel-performed to shorten the processing time.
Hence, actual root selection requires not simple
addition but complicated calculation.

For example, root C shown in Fig. 28 allows
5 parallel-executing image data correction processing at
step S3112 and transfer processing at step S3114. The
total processing time of root C is calculated by
subtracting the parallel processing time from the total
of times required for these processes. In other words,
10 the total processing time is shorter than the simple
sum of processing times by the parallel processing time.

Another root also allows parallel-executing color
correction processing at step S3115 and transfer
processing at step S3117, or image conversion at step
15 S3118 and transfer processing at step S3119. This
parallel processing shortens the total processing time.
Thus, for another root, the total processing time is
calculated at step S3205 shown in Fig. 29 in
consideration of the parallel processing time.

20 Since the total processing time is calculated in
this way, the performance of each apparatus influences
root selection as follows:

- ① When the performance of the digital camera 1 is low,
root A is advantageous.
- 25 ② When the transfer performance is low, root A is
advantageous.

executes control of optimally distributing, to the
digital camera, image processing which is generally
performed by the printer. This can shorten the total
time required for image printing processing in the
5 system.

<Second Embodiment>

The second embodiment according to the present
invention will be described below.

10 An image processing system in the second
embodiment has the same arrangement as that in the
first embodiment, data is asynchronously transferred
between a digital camera 1 and a printer 2, and a
detailed description thereof will be omitted. The
15 system of the second embodiment is different from that
of the first embodiment in that the printer 2 has
higher performance than the digital camera 1. The
second embodiment can increase distribution of image
processing to the printer 2.

20 In the second embodiment, similar to the first
embodiment, the digital camera 1 and printer 2 can
equally execute distribution control of image
processing using the peer-to-peer feature of the 1394
serial bus, and either apparatus can take the
25 initiative of this control.

In the second embodiment, when the peer-to-peer

connection partner of the digital camera 1 is the printer 2 exhibiting relatively high performance, distribution control is done on the initiative of the printer 2 in order to distribute image processing in accordance with the status of the printer 2.

The image processing system of the second embodiment can also execute five roots A to E shown in Fig. 28 in the first embodiment, and executes image processing by selecting any one of the roots. A root selection method in the second embodiment will be explained in detail.

Fig. 30 is a flowchart showing root selection processing in the second embodiment. An apparatus constituting the image processing system of the second embodiment can determine the type of partner apparatus by reading information of the configuration ROM of the partner apparatus by bus reset processing in system ON operation or system connection. If the partner apparatus is a "printer", the self apparatus starts subordinate processing; and if the self apparatus is a "printer", it takes the initiative of distribution control of image processing in the system, and executes the above-mentioned root selection processing under the control of a CPU 10. After printing processing starts, the printer 2 read-accesses the configuration ROM of the digital camera 1, and specifies the model of

digital camera based on the read contents. Note that the configuration ROM has already been read in connecting the apparatus, and if its contents are stored in a memory or the like, the stored contents are
5 read out.

At step S3302, whether the printer 2 has information about the model of digital camera specified at step S3301 is checked. If YES at step S3302, the process branches to S3303; and if NO, to step S3304.

10 If NO at step S3302, the printer 2 issues a processing time calculation request to the digital camera 1. This request is asynchronously transferred on the 1394 serial bus. After the printer 2 requests the response of the results and receives the
15 calculation results, the printer 2 calculates its processing time. Then, the process proceeds to step S3305. The digital camera 1 which has received the processing time calculation request calculates the processing time in the digital camera 1 for each root
20 described with reference to Fig. 28 in accordance with an image to be printed. Upon the completion of calculation, the digital camera 1 returns the processing time of each root to the printer 2.

If YES at step S3302, the printer 2 calculates at
25 step S3303 the processing time of each root in the printer 2 described with reference to Fig. 28 in

accordance with an image to be printed. Then, the process proceeds to step S3305.

At step S3305, the printer 2 calculates the total processing time of each of roots A to E shown in

5 Fig. 28. The printer 2 selects a root exhibiting the shortest total processing time at step S3306, and notifies the digital camera 1 of the selection result at step S3307 to cause the digital camera 1 to prepare for printing.

10 Image processing and transfer processing shown in
Fig. 28 start by the root which is selected in this
manner and exhibits the shortest processing time.

The total processing time of each root at step S3305 in the second embodiment must be calculated in consideration of the parallel processing time, similar to the first embodiment. Also in the second embodiment, the performance of each apparatus influences root selection, like ① to ④.

In the second embodiment, the transfer performance is high because the 1394 serial bus is used for communication between apparatuses, and ② "the transfer performance is low" is excluded. In addition, the second embodiment assumes that the printer 2 has relatively high performance, and thus ③ "the performance of the printer 2 is extremely low" is also excluded. As a result, ① "the performance of the

transfer time is about 0.25 sec by simple calculation
though the transfer speed slightly changes because
another processing is actually executed. Even after
the end of data transfer, the printer 2 spends a given
5 time until printing processing of the transferred data
ends. This modification effectively uses this idle
time till the end of printing.

In this modification, the digital camera 1
executes image processing for the same image data as
10 the transferred data in parallel with printing
processing in the printer 2 after the end of data
transfer. The digital camera 1 transfers the processed
image data to the printer 2 again in order to store the
data in a RAM 205 set in the private memory space of
15 the 1394 bus at the node of the printer 2. One of
identical data subjected to image processing by both
the printer 2 and digital camera 1 is used for printing
processing, and the other is stored in the private
memory of the printer 2.

20 More specifically, after the end of data transfer,
the digital camera 1 appropriately performs image
processing (except for transfer processing) from step
S3109 to S3118 shown in Fig. 28 for the same image data
as the transferred data. The digital camera 1
25 transfers the processed image data to the printer 2 by
any one of roots B to E, and stores it in the private

memory space in the printer 2. Note that a root used to transfer processed data in the digital camera 1, i.e., image processing to be performed is controlled based on the status of the printer 2.

5 Fig. 31 is a flowchart showing processing after the start of printing operation in the printer 2. This processing is controlled by the CPU 10 of the printer 2.

 After printing operation starts, image data processed by the printer 2 is read out from a RAM 12 or
10 the internal image memory (not shown) of a data processing unit 13 at step S3801, and a printer driving unit 15 executes printing operation at step S3802. Whether all the printing operations end is checked at step S3803, and if Y at step S3803, printing processing
15 ends at step S3804.

 If N at step S3803, the process proceeds to step S3805 to check whether the image data processed by the printer 2 is stored in the image memory. If Y at step S3805, the process returns to step S3802 to continue
20 printing operation. If N at step S3805, the process advances to step S3806 to check whether the processed image data is stored in the private memory (RAM 205) mounted in the printer 2. If Y at step S3806, the image data is printed at step S3802. If N at step
25 S3806, the process returns to step S3805 to wait for data to be printed.

embodiment has the same arrangement as that in the first embodiment, data is asynchronously transferred between a digital camera 1 and a printer 2, and a detailed description thereof will be omitted.

5 Optimal distribution of image processing between
apparatuses constituting the system is controlled by
the digital camera 1 in the first embodiment, and by
the printer 2 in the second embodiment. The third
embodiment concerns a method of determining which of
10 the apparatuses controls optimal distribution of image
processing between the apparatuses.

The outline of the determination method will be explained. Assume that each of the digital camera 1 and printer 2 has information about the model of connectable partner apparatus, and the partner model information contains in advance rank information representing whether the performance of the partner apparatus is higher or lower than the performance of the self apparatus. If the performance of the self apparatus is higher based on this rank information, the self apparatus controls distribution of image processing. If the performance of the self apparatus is lower, the partner apparatus controls distribution of image processing. Fig. 32 is a flowchart showing control apparatus determination processing for distribution of image processing. Processing shown in

first embodiment, data is asynchronously transferred between a digital camera 1 and a printer 2, and a detailed description thereof will be omitted.

Generally in performing printing processing in a system constituted by connecting a personal computer (to be referred to as a PC hereinafter) to a printer, the PC must quickly complete printing processing to perform another operation. Considering an increase in the throughput of printing processing in this system, the data transfer time from the PC to the printer must be shortened. Further, the processing and operation speeds on the printer side and the capacity of the printer buffer must be increased.

In the system of the fourth embodiment constituted by connecting the digital camera and printer, the printing processing time on the printer side must be shortened to increase the total throughput.

Similar to the first embodiment, the fourth embodiment uses the 1394 serial bus to enable high-speed data transfer. To increase the throughput of the sequence of printing processing, sharing of image processing between the digital camera 1 and the printer 2 is important. In the fourth embodiment, therefore, decompression processing of compressed data is appropriately shared between the digital camera 1 and the printer 2. The fourth embodiment will be

described based on the following assumption. That is,
data transfer via the 1394 serial bus is sufficiently
fast. In addition, printing operation in the printer 2
is sufficiently fast, and the printer 2 may wait for
5 processing depending on the contents of image
processing. The digital camera 1 holds image data
compressed in the JPEG format.

The sequence of printing processing in the fourth
embodiment will be described in detail.

10 Figs. 33A and 33B are flowcharts showing details
of the sequence of printing processing in the fourth
embodiment. Fig. 33A shows processing in the digital
camera 1, and Fig. 33B shows processing in the printer
2.

15 Processing in the digital camera 1 shown in
Fig. 33A will be explained.

If printing processing starts at step S3501, the
digital camera 1 reads out JPEG data to be printed from
an image memory (not shown) at step S3502, and divides
20 the JPEG data into predetermined blocks at step S3503.
At step S3504, the digital camera 1 detects the state
of an I/F 3. If the I/F 3 is in a ready state in which
data transfer is possible, the process proceeds to step
S3505; and if the I/F 3 is in a standby state (busy
25 state) in which data transfer is impossible, to step
S3508.

The ready/busy state of the I/F 3 is determined based on whether the print buffer of the printer 2 is empty. If the buffer of the printer 2 is full and has no free space, the I/F 3 is in the busy state. In
5 general, the buffer of the printer 2 has a free space at the initial stage of printing processing, and the I/F 3 is in the ready state in which data transfer is possible. Thus, the process branches to step S3505 at the initial stage of printing.

10 The digital camera 1 notifies the printer 2 of transfer of the JPEG data at step S3505, and transfers the JPEG data to the printer 2 via the I/F 3 in units of blocks at step S3506. If the JPEG data still remains at step S3507, the process returns to step
15 S3504 to repeat the processing. If NO at step S3507, the digital camera 1 ends processing for printing.

If the I/F 3 is in the busy state at step S3504, the digital camera 1 decompresses the remaining JPEG data in units of blocks at step S3508, and checks at
20 step S3509 whether the I/F state changes to the ready state. If the I/F 3 is still busy, the digital camera 1 repeats JPEG block decompression at step S3508. If the I/F state changes to the ready state, the process advances to step S3510.

25 The digital camera 1 notifies at step S3510 the printer 2 of transfer of RAW-RGB data obtained by

decompressing the JPEG data, and transfers the RAW-RGB data to the printer 2 via the I/F 3 in units of blocks. If the JPEG data still remains at step S3512, the process returns to step S3508 to repeat processing. If

5 NO at step S3512, processing ends.

Processing in the printer 2 shown in Fig. 33B will be explained.

If a CPU 10 of the printer 2 receives the JPEG data transfer notification (step S3505) or RAW-RGB data transfer notification (step S3510) from the digital camera 1, the CPU 10 sets or resets the internal JPEG flag. The CPU 10 sets the JPEG flag if the transferred image data to be printed is JPEG data, or resets the JPEG flag if the image data is RAW-RGB data.

15 If the printer 2 starts printing processing, it
checks at step S3513 whether image data to be printed
that has been transferred via an I/F 4 is stored in the
buffer area of a RAM 12. If NO at step S3513, the
printer 2 waits for transfer of image data; and if YES,
20 the process proceeds to step S3514.

If the JPEG flag is set in the printer 2 at step S3514, image data in the buffer is determined to be JPEG data, and the process shifts to step S3515 to decompress the JPEG data, and to step S3516.

```

25         If NO at step S3514, image data in the buffer is
        determined to be RAW-RGB data, and the process directly

```

shifts to step S3516. The printer 2 performs predetermined image processing necessary for printing at step S3516, and then executes printing processing at step S3517 to complete the sequence of printing

5 processing.

As described above, according to the fourth embodiment, the buffer state in the printer 2 is monitored via the I/F 3 during transfer of JPEG data by the digital camera 1. When the state changes to the
10 busy state in which transfer is impossible, the remaining JPEG data is decompressed to transfer RAW-RGB data.

In other words, the digital camera 1 determines the switching timing of the transfer data format, and
15 executes JPEG data decompression processing. This enables efficient printing processing in the system to increase the total throughput.

<Fifth Embodiment>

20 The fifth embodiment according to the present invention will be described.

An image processing system in the fifth embodiment has the same arrangement as that in the first embodiment, data is asynchronously transferred
25 between a digital camera 1 and a printer 2, and a detailed description thereof will be omitted.

The fifth embodiment is also based on the assumption that data transfer via the 1394 serial bus is sufficiently fast, the printer 2 may wait for processing because printing operation in the printer 2 is sufficiently fast, and the digital camera 1 holds image data compressed in the JPEG format.

Also in the fifth embodiment, decompression processing of compressed data is shared between the digital camera 1 and the printer 2, but the sharing
10 timing is determined by the printer 2.

The sequence of printing processing in the fifth embodiment will be described in detail.

Figs. 34A and 34B are flowcharts showing details of the sequence of printing processing in the fifth embodiment. Fig. 34A shows processing in the digital camera 1, and Fig. 34B shows processing in the printer 2.

Processing in the digital camera 1 shown in Fig. 34A will be explained.

20 If printing processing starts at step S3601, the
digital camera 1 reads out JPEG data to be printed from
an image memory (not shown) at step S3602, and divides
the JPEG data into predetermined blocks at step S3603.
At step S3604, the digital camera 1 checks a JPEG data
25 decompression request from the printer 2. If YES at
step S3604, the process advances to step S3607; and if

NO, to step S3605. In the fifth embodiment, no decompression request is issued by the printer 2 at the initial stage of printing processing. Thus, the process advances to step S3605 at the initial stage.

5 At step S3605, the digital camera 1 transfers JPEG data to the printer 2 via an I/F 3 in units of blocks. If the JPEG data still remains at step S3606, the process returns to step S3604 to repeat the processing. If NO at step S3606, the digital camera 1 ends processing for

10 printing.

If NO at step S3604, the digital camera 1 decompresses the remaining JPEG data in units of blocks to generate RAW-RGB data at step S3607. At step S3608, the digital camera 1 transfers the RAW-RGB data to the

15 printer 2 via the I/F 3 in units of blocks. If the JPEG data still remains at step S3609, the process returns to step S3607 to repeat processing. If NO at step S3609, processing ends.

Processing in the printer 2 shown in Fig. 34B

20 will be explained.

If the printer 2 starts printing processing, it checks at step S3610 whether image data to be printed that has been transferred via an I/F 4 is stored in the buffer area of a RAM 12. If NO at step S3610, the

25 printer 2 waits for transfer of image data to the buffer; and if YES, the process proceeds to step S3611.

NO, printing processing ends.

As described above, according to the fifth embodiment, the printer 2 monitors its buffer state during transfer of JPEG data. When the buffer changes to the buffer full state, the printer 2 issues a JPEG data decompression request to the digital camera 1. In accordance with the decompression request, the digital camera 1 decompresses the remaining JPEG data to transfer RAW-RGB data.

That is, the printer 2 determines the switching timing of the transfer data format, and requests JPEG data decompression processing of the digital camera 1. This enables efficient printing processing in the system to increase the total throughput.

<Sixth Embodiment>

The sixth embodiment according to the present invention will be described.

An image processing system in the sixth embodiment has the same arrangement as that in the first embodiment, data is asynchronously transferred between a digital camera 1 and a printer 2, and a detailed description thereof will be omitted.

The sixth embodiment is also based on the assumption that data transfer via the 1394 serial bus is sufficiently fast, the printer 2 may wait for

processing because printing operation in the printer 2 is sufficiently fast, and the digital camera 1 holds image data compressed in the JPEG format.

Also in the sixth embodiment, decompression
5 processing of compressed data is shared between the digital camera 1 and the printer 2, but the sharing timing is determined by the printer 2.

The sequence of printing processing in the sixth embodiment will be described in detail.

10 Figs. 35A and 35B are flowcharts showing details of the sequence of printing processing in the sixth embodiment. Fig. 35A shows processing in the digital camera 1, and Fig. 35B shows processing in the printer 2.

15 Processing in the digital camera 1 shown in Fig. 35A will be explained.

If printing processing starts at step S3701, the digital camera 1 reads out JPEG data to be printed from an image memory (not shown) at step S3702, and divides
20 the JPEG data into predetermined blocks at step S3703. At step S3704, the digital camera 1 checks whether it has received a decompression request flag representing a JPEG data decompression request issued by the printer 2. If YES at step S3704, the process advances to step
25 S3707; and if NO, to step S3705. In the sixth embodiment, no decompression request is issued by the

printer 2 at the initial stage of printing processing. Thus, the process advances to step S3705 at the initial stage. At step S3705, the digital camera 1 notifies the printer 2 of transfer of JPEG data, and transfers one block of JPEG data to the printer 2 via an I/F 3. If the JPEG data still remains at step S3706, the process returns to step S3704 to repeat the processing. If NO at step S3706, the digital camera 1 ends processing for printing.

10 If NO at step S3704, the digital camera 1
decompresses one block of the remaining JPEG data to
generate RAW-RGB data at step S3707. At step S3708,
the digital camera 1 notifies the printer 2 of transfer
of the RAW-RGB data obtained by decompressing JPEG data,
15 and transfers one block of the RAW-RGB data to the
printer 2 via the I/F 3. Then, the process proceeds to
step S3706.

Processing in the printer 2 shown in Fig. 35B will be explained.

20 If the printer 2 starts printing processing, it
checks at step S3709 whether image data to be printed
that has been transferred via an I/F 4 is stored in the
buffer area of a RAM 12. If NO at step S3709, the
printer 2 waits for transfer of image data to the
25 buffer; and if YES, the process proceeds to step S3710.

At step S3710, the printer 2 checks whether the

buffer becomes full (buffer full state). If YES at step S3710, the process shifts to step S3718. The printer 2 sets the JPEG data decompression request flag, and transmits it to the digital camera 1. After that, the process proceeds to step S3711. In general, the buffer has a free space at the initial stage of printing processing, so that the process proceeds to step S3711. At step S3711, the printer 2 checks whether the buffer has a free space (buffer empty state). If NO at step S3711, the process advances to step S3712; and if YES, to S3719. The printer 2 resets the JPEG data decompression request, and transmits it to the digital camera 1. Thereafter, the process proceeds to step S3712.

The printer 2 reads out at step S3712 JPEG data transferred from the digital camera 1. If the JPEG data still remains at step S3713, the printer 2 decompresses it at step S3714. If NO at step S3713, the process advances to step S3715. The printer 2 performs predetermined image processing necessary for printing at step S3715, and then executes printing processing at step S3716. If the data still remains at step S3717, the process returns to step S3710; and if NO, printing processing ends.

As described above, according to the sixth embodiment, the printer 2 monitors its buffer state

data compressed in the JPEG format.

In the fourth to sixth embodiments, JPEG data held by the digital camera 1 is transferred to the printer 2 after the JPEG data is decompressed by the digital camera if necessary. In this case, the first transferred data is JPEG data.

In general, the digital camera 1 can display data before sensed JPEG data which is compressed and held is printed. In this case, the JPEG is temporarily decompressed in display processing. Therefore, when data is printed after display processing, image data decompressed in display processing may be directly transferred to the printer 2.

If, however, the data transfer speed is not sufficiently high, like the seventh embodiment, the transfer time is prolonged with an increase in data amount to be transferred. As a result, the total throughput may decrease.

To prevent this, even if the digital camera 1 holds data which has already been decompressed, the seventh embodiment transfers the original JPEG data to the printer 2 in printing processing.

After this processing, i.e., after JPEG data is first transferred, decompression processing sharing control described in the fourth to sixth embodiments can be executed. However, if the data transfer speed

is low, decompression processing is desirably performed by only the printer 2 in order to increase the total processing speed.

As described above, according to the seventh
5 embodiment, the first data transfer in printing processing is limited to JPEG data, which can shorten the transfer time and allows the printer 2 to start printing operation at a higher timing. Accordingly, the total throughput of the system can increase.

10

<Eighth Embodiment>

The eighth embodiment according to the present invention will be described.

An image processing system in the eighth
15 embodiment has the same arrangement as that in the first embodiment, data is asynchronously transferred between a digital camera 1 and a printer 2, and a detailed description thereof will be omitted.

The eighth embodiment is based on the assumption
20 that the printer 2 may wait for processing because printing operation in the printer 2 is sufficiently fast, and the digital camera 1 holds image data compressed in the JPEG format.

In the eighth embodiment, when the first image
25 data to be printed is compressed, which of apparatuses can most efficiently decompress the data is determined

by a CPU 5 of the digital camera 1 as follows.

If the data transfer speed is sufficiently high,
i.e., equal to or higher than a predetermined value,
the data transfer time can be shortened. From this,
5 the CPU 5 determines that the digital camera 1 can more
efficiently perform JPEG data decompression processing.

If the data transfer speed is lower than the
predetermined value, the CPU 5 compares the performance
of the digital camera 1 with that of the printer 2, and
10 determines that an apparatus exhibiting higher
performance executes decompression processing. As this
performance comparison method, the CPU 5 can grasp the
performance of the printer 2 by reading the contents of
a configuration ROM in the printer 2 in connecting the
15 digital camera 1 to the printer 2, and referring to
model information described in the configuration ROM.
If the configuration ROM of the printer 2 does not
contain any model information, the printer 2 can read
the configuration ROM of the digital camera 1 to
20 determine the performance of the digital camera 1 and
that of the printer 2, and can notify the digital
camera 1 of the determination result.

If the data transfer speed is very low, the CPU 5
determines that decompression processing is efficiently
25 done by only the printer 2.

After an apparatus which decompresses the first

JPEG data is determined in accordance with the data transfer speed, printing processing by sharing described in the fourth to sixth embodiments is executed.

5 As described above, according to the eighth embodiment, which of the digital camera 1 and printer 2 can efficiently decompress the first JPEG data is appropriately determined to increase the throughput of printing processing.

10 In the above-described embodiments, the network is constructed using a serial interface defined by IEEE 1394. However, the present invention is not limited to this, and can also be applied to a network constructed using an arbitrary serial interface such as a universal
15 serial bus (USB).

[Other Embodiment]

The present invention may be applied to a system constituted by a plurality of devices (e.g., a host
20 computer, interface device, reader, and printer) or an apparatus comprising a single device (e.g., a copying machine or facsimile apparatus).

The object of the present invention is realized even by supplying a storage medium (or recording medium)
25 storing software program codes for realizing the functions of the above-described embodiments to a system

or apparatus, and causing the computer (or a CPU or MPU)
of the system or apparatus to read out and execute the
program codes stored in the storage medium. In this
case, the program codes read out from the storage medium
5 realize the functions of the above-described embodiments
by themselves, and the storage medium storing the
program codes constitutes the present invention. The
functions of the above-described embodiments are
realized not only when the readout program codes are
10 executed by the computer but also when the operating
system (OS) running on the computer performs part or all
of actual processing on the basis of the instructions of
the program codes.

The functions of the above-described embodiments
15 are also realized when the program codes read out from
the storage medium are written in the memory of a
function expansion board inserted into the computer or a
function expansion unit connected to the computer, and
the CPU of the function expansion board or function
20 expansion unit performs part or all of actual processing
on the basis of the instructions of the program codes.

When the present invention is applied to the
above storage medium, the storage medium stores program
codes corresponding to the flowcharts shown in Figs. 29
25 to 35B.

As many apparently widely different embodiments

WHAT IS CLAIMED IS:

1. An image processing system in which first and second image processing apparatuses are connected via a serial bus,

5 wherein said first image processing apparatus comprises control means for controlling distribution of image processing between said two apparatuses on the basis of performance of said first image processing apparatus and performance of said second image
10 processing apparatus.

2. The system according to claim 1, wherein said first and second image processing apparatuses can commonly execute a plurality of image processes, and

15 said control means distributes the plurality of image processes to said first and second image processing apparatuses.

3. The system according to claim 2, wherein when said first image processing apparatus has higher performance,
20 said control means distributes many image processes to said first image processing apparatus.

4. The system according to claim 3, wherein said control means acquires apparatus information of said second image processing apparatus via said serial bus,
25 and controls distribution of image processing in said first and second image processing apparatuses on the

said second image processing apparatus is an image output apparatus for outputting the image data transferred from said image input apparatus via said serial bus.

5 10. The system according to claim 1, wherein
said second image processing apparatus is an image input apparatus for inputting image data, and
said first image processing apparatus is an image output apparatus for outputting the image data
10 transferred from said image input apparatus via said serial bus.

11. The system according to claim 1, wherein the image data is isochronously transferred.

12. The system according to claim 1; wherein said
15 serial bus is a bus compatible or complying with the IEEE 1394 standard.

13. The system according to claim 1, wherein said serial bus is a bus compatible or complying with the USB standard.

20 14. An image processing apparatus connected to another image processing apparatus via a serial bus, comprising:

detection means for detecting performance of said another image processing apparatus;

25 determination means for determining optimal distribution of image processing between said apparatus

and said another image processing apparatus on the basis of a detection result; and

image processing means for performing image processing on the basis of a determination result.

- 5 15. An image processing apparatus connected to another image processing apparatus via a serial bus, comprising:

notification means for notifying said another image processing apparatus of performance of said
10 apparatus;

reception means for receiving distribution of image processing determined in said another image processing apparatus; and

image processing means for performing image
15 processing on the basis of the received distribution of image processing.

16. A control method of an image processing system in which first and second image processing apparatuses are connected via a serial bus, comprising the step of:

20 in the first image processing apparatus, controlling distribution of image processing between the two apparatuses on the basis of performance of the first image processing apparatus and performance of the second image processing apparatus.

- 25 17. A recording medium which records a control program of an image processing system in which first

and second image processing apparatuses are connected via a serial bus, wherein the program comprises at least:

a code of controlling, in the first image
5 processing apparatus, distribution of image processing between the two apparatuses on the basis of performance of the first image processing apparatus and performance of the second image processing apparatus.

18. An image processing system in which first and
10 second image processing apparatuses are connected via a serial bus,

wherein said first and second image processing apparatuses respectively comprise first and second control means for controlling distribution of image
15 processing between said two apparatuses, and determine which of said first and second control means acquires control.

19. The system according to claim 18, wherein the control is determined to be given to an apparatus
20 exhibiting higher performance.

20. The system according to claim 18, wherein
said first and second image processing apparatuses can commonly execute a plurality of image processes, and
25 said first and second control means distribute the plurality of image processes to said first and

second image processing apparatuses.

21. The system according to claim 20, wherein when
said first image processing apparatus has higher
performance, said first and second control means
5 distribute many image processes to said first image
processing apparatus.

22. The system according to claim 21, wherein said
first and second control means acquire pieces of
apparatus information of partner apparatuses via said
10 serial bus, and control distribution of image
processing in said first and second image processing
apparatuses on the basis of the pieces of apparatus
information.

23. The system according to claim 22, wherein the
15 pieces of apparatus information contain pieces of
performance information of the partner apparatuses.

24. The system according to claim 23, wherein said
first and second control means calculate a time
required for each image process in each of said first
20 and second image processing apparatuses, and control
distribution of image processing in said first and
second image processing apparatuses so as to minimize a
total processing time of the image processes.

25. The system according to claim 18, wherein
25 connection IDs are uniquely determined every time
said first and second image processing apparatuses are

connected to the system, and

which of said first and second control means acquires the control is determined based on the connection IDs.

5 26. The system according to claim 18, wherein said first image processing apparatus is an image input apparatus for inputting image data, and

10 said second image processing apparatus is an image output apparatus for outputting the image data transferred from said image input apparatus via said serial bus.

27. The system according to claim 26, wherein the image data is isochronously transferred.

15 28. An image processing system in which first and second image processing apparatuses are connected via a serial bus, wherein

image data processed in said first image processing apparatus is stored in storage means under management of said serial bus, and

20 said second image processing apparatus selects either of the image data stored in said storage means and image data processed by said second image processing apparatus. .

25 29. The system according to claim 28, wherein said storage means is incorporated in said first image processing apparatus.

30. The system according to claim 28, wherein said storage means is incorporated in said second image processing apparatus.

31. The system according to claim 28, wherein said
5 serial bus is a bus compatible or complying with the IEEE 1394 standard.

32. The system according to claim 28, wherein said serial bus is a bus compatible or complying with the USB standard.

10 33. An image processing apparatus connected to another image processing apparatus via a serial bus, comprising:

control means for controlling distribution of image processing between said apparatus and said
15 another image processing apparatus; and

determination means for determining whether distribution of image processing is controlled by said control means or said another image processing apparatus.

20 34. A control method of an image processing system in which first and second image processing apparatuses are connected via a serial bus, wherein

the first and second image processing apparatuses respectively comprise first and second control means
25 for controlling distribution of image processing between the two apparatuses, and determine which of the

first and second control means acquires control.

35. A control method of an image processing system in which first and second image processing apparatuses are connected via a serial bus, wherein

5 image data processed in the first image processing apparatus is stored in storage means under management of said serial bus, and

the second image processing apparatus selects either of the image data stored in the storage means
10 and image data processed by the second image processing apparatus.

36. A recording medium which records a control program of an image processing system in which first and second image processing apparatuses having first
15 and second control means for controlling distribution of image processing between the apparatuses are connected via a serial bus, wherein the program comprises at least:

a code of determining which of the first and
20 second control means acquires control.

37. A recording medium which records a control program of an image processing system in which first and second image processing apparatuses are connected via a serial bus, wherein the program comprises at
25 least:

a code of storing image data processed in the

first image processing apparatus in storage means under management of said serial bus, and

a code of causing the second image processing apparatus to select either of the image data stored in the storage means and image data processed by the second image processing apparatus.

38. An image processing system in which an image input apparatus and an image output apparatus are connected via a serial bus, wherein

said image input apparatus comprises:

input means for inputting image data of a first format;

determination means for determining whether to convert the image data of the first format into a second format;

first conversion means for converting the image data of the first format into the second format on the basis of a determination result; and

first communication means for transmitting the image data of the first or second format to said image output apparatus, and

said image output apparatus comprises:

second communication means for receiving the image data transferred from said image input apparatus;

holding means for temporarily holding the received image data in a buffer having a predetermined

capacity;

second conversion means for, if the image data held in the buffer has the first format, converting the image data into the second format; and

5 output means for sequentially outputting the image data of the second format.

39. The system according to claim 38, wherein the first format is a compressed data format, and the second format is a data format obtained by
10 decompressing image data of the first format.

40. The system according to claim 39, wherein the first format is a JPEG format.

41. The system according to claim 38, wherein said determination means in said image input apparatus
15 determines whether to convert a format of the image data on the basis of an empty state of the buffer in said image output apparatus.

42. The system according to claim 41, wherein said determination means determines to convert the format of
20 the image data when the buffer is full.

43. The system according to claim 42, wherein said determination means determines to convert the format of the image data when said serial bus is detected to be busy in said first communication means.

25 44. The system according to claim 42, wherein
 said second communication means notifies said

image input apparatus of buffer information
representing the empty state of the buffer, and

5 said determination means determines whether to
convert the format of the image data on the basis of
the buffer information.

45. The system according to claim 44, wherein

10 said second communication means issues an image
data format conversion request to said image input
apparatus on the basis of the empty state of the buffer,
and

 when the format conversion request is received,
said determination means determines to convert the
format of the image data.

15 46. The system according to claim 45, wherein said
second communication means issues the format conversion
request when the buffer is full.

47. The system according to claim 38, wherein

20 said determination means determines in units of
predetermined blocks whether to convert a format of the
image data, and

 each of said conversion means converts the image
data of the first format into the second format for all
blocks after a block said determination means
determines to convert.

25 48. The system according to claim 38, wherein

 said determination means determines in units of

predetermined blocks whether to convert a format of the image data, and

each of said conversion means converts the image data of the first format into the second format for only a block said determination means determines to convert.

49. The system according to claim 47, wherein said determination means determines not to convert the format of the image data for a first block in the image data.

50. The system according to claim 47, wherein said image input apparatus further comprises:

decision means for comparing performance of said first conversion means with performance of said second conversion means for a first block in the image data, and deciding to perform conversion processing by conversion means exhibiting higher performance.

51. The system according to claim 38, wherein said
serial bus is a bus compatible or complying with the
20 IEEE 1394 standard.

52. The system according to claim 38, wherein said serial bus is a bus compatible or complying with the USB standard.

53. An image processing apparatus connected to
25 another image processing apparatus via a serial bus,
comprising:

input means for inputting image data of a first
format;

determination means for determining whether to
convert the image data of the first format into a
5 second format;

conversion means for converting the image data of
the first format into the second format on the basis of
a determination result; and

communication means for transmitting the image
10 data of the first or second format to said another
image processing apparatus.

54. An image processing apparatus connected to
another image processing apparatus via a serial bus,
comprising:

15 communication means for receiving image data
transferred from said another image processing
apparatus;

holding means for temporarily holding the
received image data in a buffer having a predetermined
20 capacity;

conversion means for, if the image data held in
the buffer has the first format, converting the image
data into the second format; and

output means for sequentially outputting the
25 image data of the second format.

55. A control method of an image processing system in

which an image input apparatus and an image output apparatus are connected via a serial bus, comprising:

in the image input apparatus,

the input step of inputting image data of a first
5 format;

the determination step of determining whether to convert the image data of the first format into a second format;

the first conversion step of converting the image
10 data of the first format into the second format on the basis of a determination result; and

the transmission step of transmitting the image data of the first or second format to the image output apparatus, and

15 in the image output apparatus,

the reception step of receiving the image data transferred from the image input apparatus;

the holding step of temporarily holding the received image data in a buffer having a predetermined
20 capacity;

the second conversion step of, if the image data held in the buffer has the first format, converting the image data into the second format; and

the output step of sequentially outputting the
25 image data of the second format.

56. The method according to claim 55, wherein the

first format is a compressed data format, and the second format is a data format obtained by decompressing image data of the first format.

57. The method according to claim 55, wherein the
5 determination step comprises the step of determining whether to convert a format of the image data on the basis of an empty state of the buffer in the image output apparatus.

58. A recording medium which records a control
10 program of an image processing system in which an image input apparatus and an image output apparatus are connected via a serial bus, wherein the control program comprises at least:

in the image input apparatus,
15 a code of the input step of inputting image data of a first format;
a code of the determination step of determining whether to convert the image data of the first format into a second format;
20 a code of the first conversion step of converting the image data of the first format into the second format on the basis of a determination result; and
a code of the transmission step of transmitting the image data of the first or second format to the
25 image output apparatus, and
in the image output apparatus,

a code of the reception step of receiving the
image data transferred from the image input apparatus;

a code of the holding step of temporarily holding
the received image data in a buffer having a
5 predetermined capacity;

a code of the second conversion step of, if the
image data held in the buffer has the first format,
converting the image data into the second format; and

a code of the output step of sequentially
10 outputting the image data of the second format.

ABSTRACT OF THE DISCLOSURE

In a system in which an image input apparatus and image forming apparatus are directly connected, the operation of the image input apparatus may stop during the operation of the image forming apparatus. The performance between the apparatuses is unbalanced, and the total throughput is low. According to this invention, in a system in which a plurality of apparatuses are connected via a serial bus, an apparatus having the node ID = 0 upon bus reset in connection calculates a time required for each process in each apparatus for a plurality of processes forming a series of image processes. For a plurality of patterns (process roots) for distribution of image processing between the apparatuses, the processing time is calculated for each pattern. A series of image processes are executed based on a distribution pattern exhibiting the shortest time. In the image input apparatus, the format of image data to be transferred is switched in accordance with the empty state of a buffer in the image output apparatus. This enables efficient image forming processing in the system to increase the total throughput.

008	NODE_IDS	BUS ID + NODE ID
00C	RESET_START	TO RESET BUS BY WRITING INTO THIS AREA
010~014	INDIRECT_ADDRESS, INDIRECT_DATA	REGISTER TO ACCESS ROM AREA GREATER THAN 1KB
018~01C	SPLIT_TIMEOUT	TIMER VALUE TO DETECT TIME-OUT OF SPLIT TRANSACTION
020~02C	ARGUMENT, TEST_START, TEST_STATUS	REGISTER FOR DIAGNOSIS
030~04C	UNITS_BASE, UNITS_BOUND, MEMORY_BASE, MEMORY_BOUND	NOT INSTALLED IN IEEE 1394
050~054	INTERRUPT_TARGET, INTERRUPT_MASK	REGISTER OF INTERRUPTION NOTIFICATION
058~07C	CLOCK_VALUE, CLOCK_TICK_PERIOD, CLOCK_STORBE_ARRIVED, CLOCK_INFO	NOT INSTALLED IN IEEE 1394
080~0FC	MESSAGE_REQUEST, MESSAGE_RESPONSE	REGISTER FOR MESSAGE NOTIFICATION
100~17C		RESERVATION
180~1FC	ERROR_LOG_BUFFER	TO RESERVE FOR IEEE 1394

FIG. 13
SERIAL BUS REGISTER

OFFSET (hexadecimal)	REGISTER NAME	FUNCTION
200	CYCLE_TIME	COUNTER FOR ISOCHRONOUS TRANSFER
204	BUS_TIME	REGISTER FOR TIME SYNCHRONIZATION
208	POWER_FAIL_IMMINENT	REGISTER RELATING TO POWER SUPPLY
20C	POWER_SOURCE	
210	BUSY_TIMEOUT	TO CONTROL RETRY IN TRANSACTION LAYER
214~218		RESERVATION
21C	BUS_MANAGER_ID	NODE ID OF BUS MANAGER
220	BANDWIDTH_AVAILABLE	TO MANAGE ISOCHRONOUS TRANSFER BAND
224~228	CHANNELS_AVAILABLE	TO MANAGE CHANNEL NUMBER FOR ISOCHRONOUS TRANSFER
22C	MAINT_CONTROL	REGISTER FOR DIAGNOSIS
230	MAINT_UTILITY	
234~3FC		RESERVATION

FIG. 14
SERIAL-BUS NODE RESOURCE REGISTER

OFFSET (hexadecimal)	REGISTER NAME	FUNCTION
800~FFC		RESERVATION
1000~13FC	TOPOLOGY-MAP	INFORMATION ON SERIAL BUS STRUCTURE
1400~1FFC		RESERVATION
2000~2FFC	SPEED-MAP	INFORMATION ON TRANSFER SPEED OF SERIAL BUS
3000~FFFC		RESERVATION

FIG. 15
MINIMUM FORMAT CONFIGURATION ROM

01	VENDOR ID
----	-----------

FIG. 16

GENERAL FORMAT CONFIGURATION ROM

LENGTH OF bus_info_block	LENGTH OF ROM	CRC
bus_info_block (ASCII CODE OF 1394 BUS AND INFORMATION ON WHETHER OR NOT NODE HAS CAPABILITIES OF ISCHRONOUS RESOURCE MANAGEMENT, CYCLE MASTER, AND BUS MANAGEMENT)		
root_directory (INDICATE VENDOR ID AND NODE FUNCTION)		
unit_directories (INDICATE UNIT TYPE AND DRIVER SOFT VERSION)		
root & unit_leaves		
vendor_dependent_information		

FIG. 17

REQUESTS FOR BUS ACCESS

FIG. 18

BUS ACCESS GRANTED

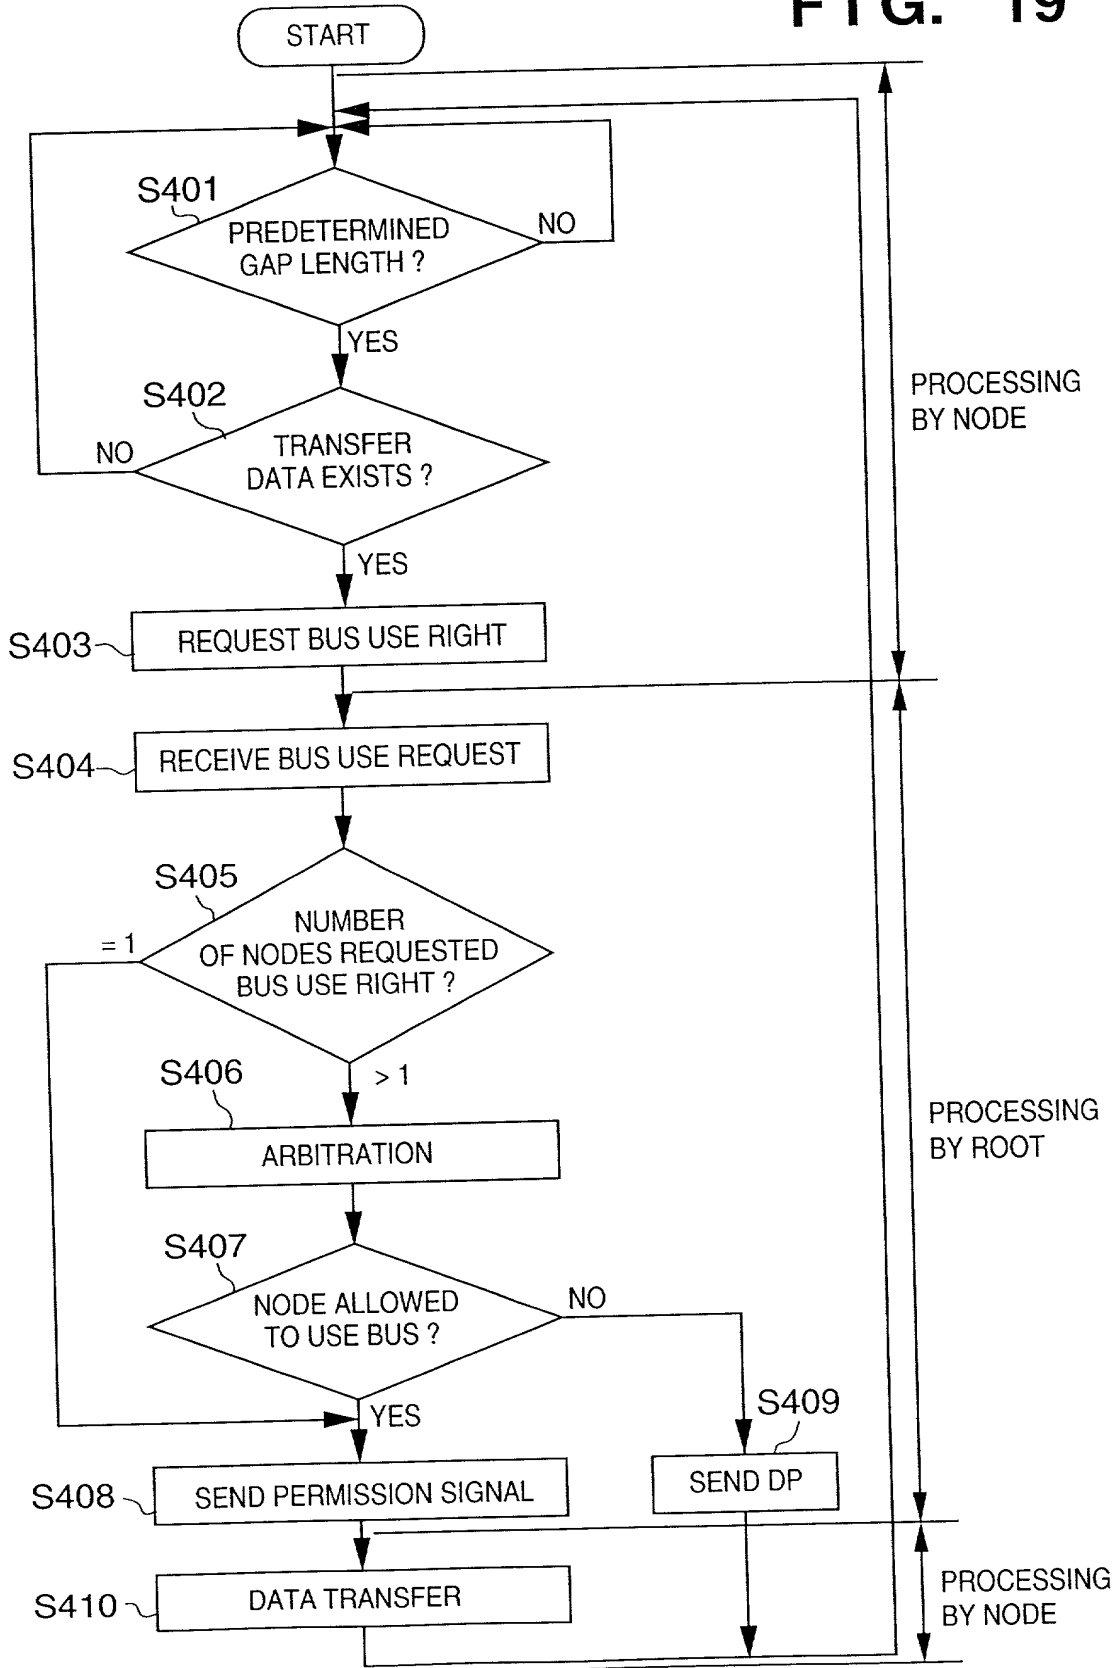

FIG. 21

FIG. 22

FIG. 23

destination_ID	t0	rt	tcode	pri
source_ID	destination_offset			
data_length	extended_tcode			
header_CRC				
data_field				
pad_field				
data_CRC				

FIG. 26

ABBREVIATION	NAME	CONTENT
destination_ID	destination identifier	ID OF DESTINATION NODE (ASYNCHRONOUS ONLY)
tl	transaction label	LABEL INDICATING A SERIES OF TRANSACTIONS (ASYNCHRONOUS ONLY)
rt	retry code	CODE INDICATING RETRANSMISSION STATUS (ASYNCHRONOUS ONLY)
tcode	transaction code	CODE INDICATING PACKET TYPE (ASYNCHRONOUS ONLY)
pri	priority	PRIORITY ORDER (ASYNCHRONOUS ONLY)
source_ID	source identifier	SOURCE NODE (ASYNCHRONOUS ONLY)
destination_offset	destination memory address	MEMORY ADDRESS OF DESTINATION NODE (ASYNCHRONOUS ONLY)
rcode	response code	RESPONSE STATUS (ASYNCHRONOUS ONLY)
quadiet_data	quadiet (4bytes) data	4-BYTE LENGTH DATA (ASYNCHRONOUS ONLY)
data_length	length of data	LENGTH OF data_field (EXCEPT pad bytes)
extended_tcode	extended transaction code	EXTENDED TRANSACTION CODE (ASYNCHRONOUS ONLY)
chanel	isochronous identifier	IDENTIFICATION OF ISOCHRONOUS PACKET
sy	synchronization code	SYNCHRONIZATION OF VIDEO IMAGE AND AUDIO INFORMATION
cycle_time_data	contents of the CYCLE_TIME register	CYCLE TIMER REGISTER VALUE OF CYCLE MASTER NODE (CYCLE PACKET ONLY)
data_field	data + pad bytes	DATA STORAGE (ISOCHRONOUS AND ASYNCHRONOUS)
header_CRC	CRC for header field	CRC FOR HEADER
data_CRC	CRC for data field	CRC FOR DATA
tag	tag label	ISOCHRONOUS PACKET FORMAT

NOTED "65505960"
